Table 3 Primary aluminium smelter capacity 1996-2001	

A. Introduction

1. In 1995 and 1996, the UNCTAD secretariat published notes on "Recent and planned changes in production capacity for bauxite, alumina and aluminium" (UNCTAD/COM/RDS/1 and 4 respectively). The notes were intended to provide a continuation of a similar service formerly provided by the secretariat of the International Bauxite Association (IBA), which ceased its activities at the end of 1994. The notes were distributed to the member Governments of UNCTAD, as well as to about 100 companies, institutions and individuals interested in the bauxite/alumina/aluminium industry. Readers were invited to comment on the usefulness and accuracy of the information. The replies received were all positive, and accordingly, it has been decided to continue the service for the time being on a trial basis. In order to be able to assess the usefulness of the continued regular publication of this type of note, the UNCTAD secretariat would once again welcome any comments on its scope, format and contents and usefulness. A reply form is included at the end of the note. Given the scarcity of information on the bauxite/alumina/aluminium industry in some countries, errors concerning the capacity of individual plants are unfortunately unavoidable, and the UNCTAD secretariat would accordingly be most grateful for indications of possible errors.

2. The present note uses the same format as the ones previously published. The bulk of the note consists of three tables showing capacity developments for bauxite, alumina and primary aluminium respectively during the period 1996 to 2001. The tables are based on information on production capacities and investment plans available to the UNCTAD secretariat, mainly from trade journals. A commentary on the tables is provided in section C below in summary form.

B. Definitions

3. With the exception of data for bauxite mines, capacity refers to nominal or "nameplate" capacity. While alumina refineries and primary aluminium smelters may from time to time exceed their nominal production capacities, sometimes for many consecutive years, an attempt to estimate "actual" or "real" capacities is likely to lead to inconsistencies and create confusion. In the case of bauxite mines, however, nominal capacity figures may not be very relevant, given the ease with which output can often be changed. Accordingly, bauxite mine production capacities refer to "real" capacity, as concluded from historical production figures. Capacities are expressed in thousand metric tons per year at the end of the year.

4. For bauxite mines, production capacity data refer to the gross weight (that is, not the aluminium or alumina content) of saleable products. It should be noted that the data may in some cases refer to dry weight (not including the moisture content of the material) rather than total weight, since it has not been possible to standardize the data. Data on a few mines producing non-bauxite raw materials used in alumina refineries have been included, although the capacity data are shown within parentheses and are not included in the totals. Production capacity data for alumina refineries refer to gross weight (not aluminium content) of saleable products. For aluminium, the data refer to primary aluminium in whatever form it is commercialized. Information on some production facilities which have closed as a result of war or civil disturbance has been included. Where it is unlikely that the production facility in question could be re-opened without a major reconstruction effort, its capacity is shown within parentheses and is not included in the totals.

5. Future additions to capacity have been included where there is a reasonably high probability of the investment taking place, for instance, because construction has started, financing has been secured or government approvals have been obtained. Clearly, information on projects which are not planned to enter production until late in the period is less certain. For the sake of completeness, information has also been provided on some projects which are unlikely to enter into production during the period, in which case their capacity is shown as zero.

C. Summary of recent and expected developments in production capacity

6. The following table summarizes expected capacity developments during the period 1996 to 2001.

World production capacity for bauxite, alumina and aluminium 1996-2001 (thousand metric tons per year)

Product	Capacity in 1996	Changes		
		1997	1998	1999-2001
Bauxite	137,834	1,000	1,500	13,400
Alumina	51,215	780	100	11,208
Primary aluminium	22,972	487	360	2,608

1. Bauxite

7. World bauxite capacity is estimated to have increased by 1 million tons in 1997. The only capacity expansion took place in Suriname, where the depleted Accaribo deposit was replaced by the nearby Lelydorp III deposit with a higher capacity. Other expansions that were planned have not been implemented, owing to a relatively weak market.

8. In 1998, production capacity is expected to increase by 1.5 million tons as a result of the expansion of the Boke/Sangaredi mine in Guinea.

9. Over the period from 1999 until the end of 2001, world bauxite production capacity is expected to increase by 13.4 million tons. India accounts for about half the expansion with at least one new mine. Additional mining capacity may be added in India later, since several integrated bauxite/alumina/aluminium operations are being planned in the state of Orissa. In addition, capacity at the Panchpatmali mine is expected to increase by 2.4 million tons. A new mine will be opened in 1999 in Queensland, Australia by Alcan. Capacity is expected to increase at a number of existing mines, including Huntly (6.1 million tons, replacing capacity at the Jarrahdale mine, which will be closed at the end of 1998) and Weipa in Australia (2.5 million tons) and in Jamaica, where a new mine may also be constructed early in the next century. It is also likely that there will be some expansion of bauxite production capacity in China, although exact details are not known.

2. Alumina

10. World alumina refining capacity is estimated to have increased by 780,000 tons in 1997, or by 1.5 per cent. The expansion of the Alumar refinery in Brazil accounts for more than half of this, or 400,000 tons, with the rest being made up by smaller extensions in China, India and Jamaica.

11. In 1998, production capacity for alumina is expected to increase by only 100,000 tons, accounted for by an expansion at the Damanjodi refinery in India.

12. During the period 1999-2001, alumina capacity is expected to increase by 11.2 million tons. Again, a large portion of the capacity increase (3.6 million tons) is expected to take place in India, where three new refineries are planned to enter production. In addition, capacity at the Damanjodi refinery is planned to increase further by 680,000 tons. Three more refineries, all part of integrated operations, are planned for early in the next century. Continued expansion is expected in China, where known plans would result in the addition of 790,000 tons of capacity. In Australia, capacity increases are planned at the Gladstone (0.3 million tons), Gove (0.3 million tons), Wagerup (1.3 million tons) and Worsley (1.4 million tons) refineries. In Latin America and the Caribbean, capacity expansions are planned at the Alumar refinery in Brazil (700,000 tons), the Alpart (550,000 tons), Ewarton (288,000 tons), Kirkvine (300,000 tons) and Jamalco (300,000 tons) refineries in Jamaica, and the Mantanzas refinery in Venezuela (1 million tons). Finally, capacity is planned to increase by 250,000 tons at the Pavlodar refinery in Kazakhstan.

3. Aluminium

13. In late 1997, a little more than 1 million tons of primary aluminium smelter capacity, representing 4.5 per cent of world capacity, was temporarily closed due to the market situation. In most cases, the closures were initially made in response to the earlier Memorandum of Understanding between the governments of several aluminium producing countries. Although the Memorandum of Understanding is no longer in force, market conditions have kept a large proportion of the smelters concerned from re-opening. Most of the continued cutbacks concerned smelters in the United States. Some of the capacity shut down earlier was put back in production in 1996 and 1997, particularly in Australia, France and Norway. Since information about the status of cutbacks is not available in some cases, the figures are uncertain. This is the case in particular for the Russian Federation, where production was curtailed in 1994 by an amount corresponding to an annual capacity of 326,000 tons. It is not known exactly how much of this cutback remains in force. More importantly, several other smelters, mainly in the other republics of the former USSR and in the countries formerly constituting Yugoslavia, operated at reduced capacity or were shut down due to war, civil unrest or technical problems. Total capacity was about 23.5 million tons at the end of 1997, and it is estimated that total production in the year will be slightly about 21 million tons, or about 4.5 per cent more than in 1996.

14. World production capacity is expected to have increased by 487,000 tons in 1996, or by 2.1 per cent. Two new smelters entered into production during the year, the Al Mahdi smelter in the Islamic Republic of Iran (final capacity to be 220,000 tons) and the Alscon smelter in Nigeria (final capacity 193,000 tons). Capacity was expanded at several smelters, including the Straumsvik smelter in Iceland (62,000 tons), the Årdal and Karmøy smelters in Norway (12,000

and 35,000 tons), the Gladstone smelter in Australia (230,000 tons), the Nag Hammadi smelter in Egypt (50,000 tons) and the Alba smelter in Bahrain (17,000 tons).

15. In 1998, aluminium production capacity is expected to increase by 360,000 tons. The only new smelters expected to enter production are the Columbia Ventures Corporation's smelter in Iceland (60,000 tons) and the smelter at Qeshm (28,000 tons) in the Islamic Republic of Iran. The latter smelter, which was earlier located in Slovakia and which was closed to be replaced by a new smelter with better environmental performance, is being rebuilt at Qeshm. Most of the increase in capacity is due to completions of projects already under way, including the ones already mentioned in Nigeria and the Islamic Republic of Iran, and to expansions of existing plants. The latter include the Tomago smelter in Australia (60,000 tons) and Hindustan Aluminium's smelter at Renukoot (32,000 tons)

16. During the years 1999 to 2001, production capacity is expected to increase by 2.6 million tons. Of this, more than 1.6 million tons would be added through expansions of existing smelters in Argentina, Australia, Azerbaijan, Brazil, Cameroon, China, India, Norway, the Russian Federation, Spain, Turkey and Venezuela. China would account for about 0.5 million tons through expansions of existing capacity alone. The new smelters in the Islamic Republic of Iran and Nigeria will also reach full capacity during the period. Three new smelter projects with a combined capacity of 710,000 tons are reasonably certain to be implemented: in Chile (270,000 tons), Kuwait (200,000 tons) and Mozambique (240,000 tons). Three other projects with a total capacity of 555,000 tons may be completed before the end of the year 2001: in China (two smelters with a total capacity of 355,000 tons) and Kazakhstan (200,000 tons). Other smelter projects, including in China, India and Oman are still at a relative early stage and are less likely to be completed during the period. One smelter, at Steg in Switzerland (18,000 tons), will probably be closed in 1999.

D. Market outlook

17. Aluminium stocks decreased in both 1996 and 1997 as a result of the closures mentioned earlier and relatively strong growth in consumption in 1997. London Metal Exchange (LME) stocks decreased by 367,000 tons in 1996 and by 219,000 tons in the first nine months of 1997. Inventories of unwrought aluminium held directly by producers as reported by the International Primary Aluminium Institute (IPAI) decreased by 305,000 tons in 1996 but did not change significantly during the first nine months of 1997. Thus, the reduction in stocks continued well into 1997, although stocks appeared to have levelled out in the second half of the year, probably as a result both of new capacity entering into production and consumption growing at a slower rate than expected. At the end of the year, it appears that production and consumption rates are more or less in balance. Prices levelled out in 1996 after having fallen in 1995. In 1997, they increased through most of the year, reaching a peak of US\$ 1,788 per ton in early August, following which they fell to levels below US\$ 1,500 in December. Uncertainty about worldwide economic growth rates and the potential for rapid re-opening of the closed-down capacity may preclude any significant increases in prices in the near future, in spite of stocks being close to the level desired for operations. For the period until 2001, assuming that primary aluminium consumption increases at a rate close to the historical average, that is, an annual rate of between 2.5 and 3.5 per cent, anticipated capacity increases of 3 million tons over the same period should be sufficient to meet demand and hold prices within a relatively narrow band.

18. The alumina market has been in balance over the past two years, with prices stable at historically low levels. While anticipated additions to capacity over the next two to three years are small compared to the expected increase in demand, there is considerable potential for gradual expansion of capacity in existing refineries. Moreover, the re-opening of the St. Croix smelter in the U.S. Virgin Islands, which was largely unexpected, adds to the available capacity. In the longer term, the large capacity increases foreseen over the period 1999 to 2001 are likely to be sufficient to avoid a shortfall of alumina.

19. Bauxite capacity and production are expected to grow at rates sufficient to meet the requirements of alumina refineries, in particular since major additions to capacity are expected to take place over the period 1999 to 2001.
