## Annex: Data and methodology

To identify the opportunities for countries to build their productive capacities and promote structural transformation, this report identifies the products that require a set of capabilities that is somewhat similar to that required to produce the current product mix. These products are located in the product space nearby to the existing product mix.

The measure of proximity between products $A$ and $B\left(\Phi_{A B}\right)$ in the product space is calculated using a method similar to that proposed by Hidalgo et al (2007), as the minimum value between the conditional probability $P(A \mid B)$ of a country producing $A$ given that it produces $B$ and the conditional probability $P(B \mid A)$ of a country producing $B$ given that it produces $A$ :

$$
\begin{equation*}
\Phi_{A B}=\Phi_{B A}=\min (P(A \mid B), P(B \mid A)) \tag{1}
\end{equation*}
$$

The proximity between two products, therefore, ranges from $0 \%$, in the case in which no country produces both products, to $100 \%$ in the case in which all countries that produce one good also produces the other.

To identify the products that are located nearby in the product space of each country, a value has to be chosen for the threshold of proximity between products that correspond to a "usual" distance covered during the diversification process. In this report this value is $80 \%$, meaning that eight in every ten countries that export one of the products also exports the other.

The Report then identifies the potential new products that are nearby in the product space and that, in addition, are more complex. To measure product complexity, this paper uses the method of reflections proposed by Hidalgo \& Hausmann (2009). The method constructs a bipartite network of countries and products that they produce and iteratively calculate a generalized measure of diversification and ubiquity as follows:

$$
\begin{array}{ll}
K_{c, N}= & \frac{1}{K_{c, 0}} \sum_{p} M_{c p} K_{p, N-1} \\
\text { (Generalized measure of diversification) } \\
K_{p, N}=\frac{1}{K_{p, 0}} \sum_{c} M_{c p} K_{c, N-1} & \\
\text { (Generalized measure of ubiquity) } \tag{3}
\end{array}
$$

Where $M_{c p}$ is 1 if country $c$ makes product $p$ and 0 otherwise, $K_{c, 0}$ is the number of products produced by country $c$ and $K_{p, 0}$ is the number of countries that make product $p$.

The measure of product complexity ( $P C O M P$ ) is taken as the normalized value of the $K_{p}$ value of the $5^{\text {th }}$ iteration of the method of reflections:

$$
\begin{equation*}
P C O M P=\frac{K p 5-<K p 5>}{s d(K p 5)} \tag{4}
\end{equation*}
$$

Where $<K_{p 5}>$ is the mean and $s d\left(K_{p 5}\right)$ is the standard deviation of the distribution of $K_{p 5}$. The $K_{p 5}$ is used because such iterative analysis is carried out until no further information is obtainable from this method, which depends on the structure of the network and for the dataset used happens on the $5^{\text {th }}$ iteration.

The analysis considers the price incentives that entrepreneurs face when choosing between different potential new economic activities, by estimating both export and import substitution opportunities. The assumption is that entrepreneurs face price incentives when choosing between different potential new economic activities. New products with higher demand potential are more likely to be selected, other things being equal.

To estimate the product's export potential, this paper uses an export opportunity measure of potential new products (Freire, 2017). This measure is a monetized type of overlap index designed to measure the degree to
which the potential new exports of one country match the expanding import markets of another. A higher degree of export opportunity of potential new products indicates more favorable prospects for trade expansion towards the new products given the past rate of growth of their import markets.

The indicator $(X O P)$ is defined as the sum of the differences of the shares of the sectoral imports of the import country in total world imports between two periods. Formally:

$$
\begin{equation*}
X O P=\sum_{i} G_{i s d}^{t 0, t 1} \times M^{2019} \tag{5}
\end{equation*}
$$

Where $M^{20119}$ is the total imports by all countries in all products in year 2019, and $G_{i s d}^{t 0, t 1}$ is the growth in the global share of imports $m$ of industry $i$ in country $d$ in the period between t0 (2018) and $t 1$ (2019). For any pair of countries, only the sectors that meet the following criteria are included: 1) share of the sectoral imports in total world imports has increased between the two periods, and 2) that sector represents a potential new product for the export country. Formally:

$$
G_{i s d}^{t 0, t 1}=\frac{m_{i d}^{t 1}}{M^{t 1}}-\frac{m_{i d}^{t 0}}{M^{t 0}} \text { if } \Phi_{i j}>85 \% \text { for some product } j \text { in the country's existing product mix and }
$$

$\frac{m_{i d}^{t 1}}{M^{t 1}}>\frac{m_{i d}^{t 0}}{M^{t 0}}$, and zero otherwise.

Where $s$ is the source country, $d$ is the destination country.
To apply the method of reflections and to calculate the proximity between products in the product space, data on country's production is required. Since there are few systematically disaggregated production data that covers the less industrialized developing and least developed countries, this paper uses as a proxy the disaggregated trade data from United Nations COMTRADE using Harmonized System code (HS 2002) at 6-digit level covering 233 economies for the year 2019. The data is further disaggregated by quantity unit code and by unit price range using the methodology proposed in Freire (2017). At the end of this procedure, the dataset contains 45,841 products in 2019, each product represented by an 8 -digit classification code in which the first six digits correspond to the 6-digit HS 2002 code, the seventh digit corresponds to the quantity unit code of the product and the eighth digit represents the unit value group that includes the unit value of the product.
